A 4-bit synchronous counter using JK flip-flops. In synchronous counters, the clock inputs of all the flip-flops are connected together and are triggered by the input pulses. Thus, all the flip-flops change state simultaneously (in parallel). The circuit below is a 4-bit synchronous counter. The J and K inputs of FFO are connected to HIGH.

The 4-bit counter starts incrementing from 4'b0000 to 4'h1111 and then rolls over back to 4'b0000. It will keep counting as long as it is provided with a running clock and reset is held high. The rollover happens when the most significant bit of the final addition gets discarded.

Counter (digital) - Wikipedia

With a synchronous circuit, all the bits in the count change synchronously with the assertion of the clock. Examples of synchronous counters are the Ring and Johnson counter. It can be implemented using D-type flip-flops or JK-type flip-flops. The circuit below uses 2 D flip-flops to implement a divide-by-4 ripple counter ( $2^n = 2^2 = 4$ ).

The characteristic equation for the D-FF is:  
 $Q^+ = D$ . We need to design a 4 bit up counter. So, we need 4 D-FFs to achieve the same. Let's draw the state diagram of the 4-bit up counter. Let's construct the truth table for the 4-bit up counter using D-FF

BCD Counter Using D Flip Flops - Peter Vis  
Using The D-type Flip Flop For Frequency  
Division. One main use of a D-type flip flop  
is as a Frequency Divider. If the Q output on  
a D-type flip-flop is connected directly to  
the D input giving the device closed loop  
"feedback", successive clock pulses will make  
the bistable "toggle" once every two clock  
cycles.
