Chromatography methods based on partition are very effective for separation, and identification of small molecules as amino acids, carbohydrates, and fatty acids. However, affinity chromatographies (ie. ion-exchange chromatography) are more effective in the separation of macromolecules as nucleic acids, and proteins.

The Fibers in GFRC- How They Work. The glass fibers used in GFRC help give this unique compound its strength. Alkali resistant fibers act as the principle tensile load carrying member while the polymer and concrete matrix binds the fibers together and helps transfer loads from one fiber to another.

For example: In our daily life, the filtration method is used, while preparing tea. We use a sieve at home to separate tea leaves from the water. Tea is obtained as the filtrate through the sieve pores. Centrifugation. Sometimes, the solid particles in a liquid are minute enough to pass through a filter paper.

- Particles smaller than we can detect by visual or sieve analysis methods.
- Silts are very fine bulky particles like sands – they are rock and mineral fragments – they are reasonably inert.
- Clays are minerals that are the product of chemical weathering of feldspar, ferromagnesian, and mica minerals.

Use of the bootstrap idea goes back at least to Simon who used it as a tool to teach statistics. But the properties of the bootstrap, its connection to the jackknife and other resampling methods, were not realized until Efron (1979). Similar resampling methods such as the jackknife and subsampling go back to the late 1940s and 1960s
