Back to the BFO method. The idea is to measure the frequency of a LC oscillator. By fixing the capacitance C, any change in the oscillator frequency means the inductance L has changed due to some metal object. The oscillator frequency is a trade-off of importance. A low frequency (10KHz) is best to penetrate the soil.

Carl Moreland and George Overton, long time denizens of the Geotech website and MD designers in their own right wrote the book, "Inside the Metal Detector." Not only does the book cover theory, but design principles and actual projects as well. But again, the principal mechanisms presented have their own biases built into the explanations.

BFO Theory. The beat-frequency oscillator, or BFO, is generally the simplest type of metal detector and is a good starting point for learning how metal detectors work. The dominant technology throughout the 60's and much of the 70's, the BFO has now practically vanished from the market and can only be found in the poorest quality toy detectors.

Even the simplest 3-transistor BFO detector is more complex than the Examiner. The Examiner does have the appearance of a dowsing rod, and also operates exactly like a dowsing rod. In fact, when all of the non-functional eye candy is removed from the device — the "circuit", the control knob, the unconnected pieces of wire, and the calculator — what's left is... a dowsing rod!
