\*The unit  $\text{kJ/kg}\cdot\text{K}$  is equivalent to  $\text{kPa}\cdot\text{m}^3/\text{kg}\cdot\text{K}$ . The gas constant is calculated from  $R = R_u/M$ , where  $R_u = 8.31447 \text{ kJ/kmol}\cdot\text{K}$  is the universal gas constant and  $M$  is the molar mass. Source: Specific heat values are obtained primarily from the property routines prepared by The National Institute of Standards and Technology (NIST), Gaithersburg, MD.

Standard heat pipes only transfer heat along the axis of the heat pipe, so they are best suited to cooling discrete heat sources. Vapor Chambers or High Conductivity (HiK™) Plates are used to collect heat from larger area sources, and either spread the heat, or conduct it to a cold rail for cooling. Vapor Chambers are generally used for high heat flux applications, or when genuine two ...

Figure 8a-1: The atomic structure of a water (or dihydrogen monoxide) molecule consists of two hydrogen (H) atoms joined to one oxygen (O) atom. The unique way in which the hydrogen atoms are attached to the oxygen atom causes one side of the molecule to have a negative charge and the area in the opposite direction to have a positive charge.

Keep in mind plastic is a poor conductor of heat. The heat from the plastic radiates relatively slowly into the mold steel. The heat-transfer characteristics of the mold steel and the water in the cooling lines are many times faster. The weak link in this plastic-metal-water heat-transfer system is the water's flow rate.

The specific heat capacity ( $c$ ) of a substance, commonly called its specific heat, is the quantity of heat required to raise the temperature of 1 gram of a substance by 1 degree Celsius (or 1 kelvin):  $c = \frac{q}{m \Delta T}$  Specific heat capacity depends only on the kind of substance absorbing or releasing heat.
