Geometrical optics, or ray optics, describes the propagation of light in terms of "rays" which travel in straight lines, and whose paths are governed by the laws of reflection and refraction at interfaces between different media. These laws were discovered empirically as far back as 984 AD and have been used in the design of optical components and instruments from then until the present day.

Geometrical optics is also known as ray optics. Using the term rays geometrical optics approximate the paths light travels. Rays are used to define the movement of light depending on the environments and mediums around it. Light rays travel in a straight line until they hit a medium.
