In general, MF is a process to find two factor matrices, P ? R, k×m and Q ? R, k×n, to describe a given m-by-n training matrix R in which some entries may be missing. MF can be found in many applications, but we only use collaborative filtering in recommender systems as examples.

There are many ways to see why this argument is wrong. First, in Cayley–Hamilton theorem, p(A) is an n×n matrix. However, the right hand side of the above equation is the value of a determinant, which is a scalar. So they cannot be equated unless n = 1 (i.e. A is just a scalar).

Let us begin with an example: I Suppose that we have an undirected random graph G on n vertices. I Model:There is a real symmetric matrix P = (p ij) such that Prob(fijjis an edge of G) = p ij; and edges pop up independently of each other. I A statistical question: Given a single realization of the random graph G, under what conditions can weaccurately estimate

MATRIX ESTIMATION BY USVT 5 incidentally, the proof shows that the condition  $p > n^{?1+?}$  may be im-proved to  $p > n^{?1}(\log n)^{6+?}$  (see Theorem 3.4), but I prefer to retain the present version for aesthetic reasons, especially considering that it is not a real improvement from any practical point of view.
