Skeletal muscles are organized into units called sarcomeres which are overlapping chains of two different proteins, actin and myosin. That in a nutshell is the microscopic anatomy of skeletal muscle.

Structure of Skeletal Muscle Explained in simple terms
Skeletal muscles as organs consist of muscle fibers bound by connective tissue. The connective tissue also attaches skeletal muscle to the skeleton and other tissues and transmits the force of a contraction to the moving part.

Skeletal muscles are responsible for the pumping action of the heart. Skeletal muscles support the weight of some internal organs. Skeletal muscles are responsible for guarding the openings of the digestive and urinary tracts. The contractions of skeletal muscles pull on tendons and move elements of the skeleton.

10.2 Skeletal Muscle - Anatomy and Physiology
Aponeuroses are thick membranes that separate muscles from one another. They are tough and resilient. Tendons are similar, in both function and composition, only they serve to connect muscles to bones. Both aponeuroses and tendons are capable of resisting considerable tension.

Striated skeletal muscle fibers are totally dependent upon the nervous system, however, for both their structural integrity and function. Each striated skeletal muscle fiber is supplied with a nerve fiber ending on a specialized region of the cell membrane or sarcolemma, the subneural region of the motor end plate.
