Ultimately, the strain left is the permanent plastic strain as shown in Fig. 6.13, which illustrates the initial part of the stress-strain curve. When the total deformation is small as in Fig. 6.13, the elastic and anelastic strains are significant, but can be neglected while studying large plastic deformations.

At high strain rates, the process is essentially adiabatic, and at large plastic strains, the thermal excursion associated with plastic deformation can be significant. Most high-strain-rate research has focused on low plastic strains, and the constitutive models proposed (e.g. Harding [7], Follansbee and Kocks [8], Zerilli and Armstrong [9]) are based on

Under tensile stress plastic deformation is characterized by a strain hardening region and a necking region and finally, fracture (also called rupture).

### **Plastic Deformation of Metals: 3 Modes | Metallurgy**

Deformation vs Strain | Elastic Deformation and Plastic Deformation, Hooke's law Deformation is the changing of the shape of a body due to the forces and pressure applied on it. Strain is the force created by the elasticity of an object. Both deformation and strain are two very important concepts discussed under material science.

The plastic deformation and fracture behaviour of Ti-55511 alloy subjected to high strain rate at room temperature have been reported. Results obtained from the mechanical testing show that macro shear failure occurs when strain rate is above  $1370 \text{ s}^{-1}$ , and the failure strain is about 0.16.

## **Difference Between Deformation and Strain | Compare the ...**

Main Difference – Elastic vs Plastic Deformation. Deformation is the action or process of deforming or distorting. When a force is applied to an object, the object will either compress or stretch as a response to the force. In mechanics, the force applied to a unit area is called stress. The extent of stretching or compressing (as a response to the stress) is called strain.

In engineering, deformation refers to the change in size or shape of an object. Displacements are the absolute change in position of a point on the object. Deflection is the relative change in external displacements on an object. Strain is the relative internal change in shape of an infinitesimally small cube of material and can be expressed as a non-dimensional change in length or angle of ...

The influence of increasing strain rate on the mechanical behavior and deformation substructures in metals and alloys that deform predominately by slip is very similar to that seen following quasi-static deformation at increasingly lower temperatures or due to a decrease in stacking-fault energy (? sf). The mechanical properties of plastic materials depend on both the strain (rate) and temperature. At low strain, the deformation of most solids is elastic, that is, the deformation is homogenous and after removal of the deforming load the plastic returns to its original size and shape.
