Our results are therefore unconditional in the case $s = 2$, and in particular we can obtain the expected asymptotics for the number of 4-term progressions $p_1 < p_2 < p_3 < p_4 \leq N$ of primes, and more generally for any (non-degenerate) problem involving two linear equations in four prime unknowns.

We investigate the stability of the Einstein static universe under linear scalar, vector, and tensor perturbations in the context of a deformed Hořava-Lifshitz (HL) cosmology related to entropic forces. We obtain a general stability condition under linear scalar perturbations. Using this general condition, we show that there is no stable Einstein static universe in the case of a flat ...

Laplace's equation arises in a vast array of contexts (electrostatics, harmonic functions, low-frequency acoustics, percolation theory, homogenization theory, and the study of field enhancements in vacuum insulators for example) and serves as a useful model problem for the study of general elliptic partial differential equations (PDEs). As such,

variety of ways. This constitutes a unique anomaly since the fundamental equations in physics arise from first principles. In most texts, the Schrodinger equation is termed to be "an axiom" or "a physical law analogous to Newton's second law of motion in classical physics" or a phenomenological equation that "just works" [175].

The Schwinger–Dyson equations (SDEs), or Dyson–Schwinger equations, named after Julian Schwinger and Freeman Dyson, are general relations between Green functions in quantum field theories (QFTs). They are also referred to as the Euler–Lagrange equations of quantum field theories, since they are the equations of motion corresponding to the Green's function.

Additionally in 2005, H. S. Bhat et. al. [16] applied the Lagrangian aver-aging approach to the full compressible Euler equations. Their approach was successful in that a set of Lagrangian Averaged Euler (LAE-) equations were derived. However, the equations seemed so intractable that they seemed impractical for real world applications.

Basic assumptions. The Navier–Stokes equations are based on the assumption that the fluid, at the scale of interest, is a continuum – a continuous substance rather than discrete particles. Another necessary assumption is that all the fields of interest including pressure, flow velocity, density, and temperature are differentiable, at least weakly.. The equations are derived from the basic ...

In this case, from S and T, one can again, in a natural manner, construct a Lorentzian conformal metric on the six dimensional space $(z, z_s, z_t, z_{st}, s, t)$. When the S and T satisfy equations analogous to $U[F]=0$, namely equations of the form $M[S,T]=0$, the 6-space then possesses a pair of conformal Killing fields, $\xi = \text{partial}$ with respect to s and ...
