where t is a real scalar (the time) and y a real vector (the state) and \dot{y} a real vector (the first order derivative dy/dt).. If f is a string, it is the name of a Fortran subroutine or a C compiled function. For example, if we call `ode(y0,t0,t,"fex")`, then the subroutine `fex` is called.. The Fortran routine must have the header:

The instruction is the piece of code that is evaluated each time the control variable is incremented as long as the condition within the expression is satisfied.. Let 's apply the for loop structure to our function (in a Scilab script):. `for x=1:1:5 f(x) = x^2 + sqrt(x); end.` In our example x is the index which gets incremented and also the function argument.
