We put one FPGA into each front-end assembly, so it did the feature extraction for up to 196 channels per event, then shipped the output data for multiplexing and fiber transfer. Not only did this result in a great gain in processing speed per event, it also reduced the data volume by a factor of 5: The raw waveforms are 32 bytes per channel, while the feature extracted data average six bytes.

Regarding the lifespan of FPGA systems as one poster noted earlier, how robust is the FPGA in comparison to other data storage methods? Over time, storage mediums lose their ability to actually contain what was originally programmed into them. Pressed CDs, for example, last 100 or so years. Burned CDs, a mere 5 years or up to 15 if you're lucky.
