*In this type of reservoir, the principal source of energy is a result of gas liberation from the crude oil and the subsequent expansion of the solution gas as the reservoir pressure is reduced. As pressure falls below the bubble-point pressure, gas bubbles are liberated within the microscopic pore spaces.*

*Solution-gas drive This mechanism (also known as depletion drive) depends on the associated gas of the oil. The virgin reservoir may be entirely liquid, but will be expected to have gaseous hydrocarbons in solution due to the pressure.*

*Oil reservoirs that do not initially contain free gas but develop free gas on pressure depletion are classified as solution gas drives. The solution gas drive mechanism applies once the pressure falls below the bubblepoint. Both black- and volatile-oil reservoirs are amenable to solution gas drive. Other producing mechanisms may, and often do, augment the solution gas drive.*

*A solution gas drive reservoir is one in which the principal drive mechanism is the expansion of the oil and its originally dissolved gas. The increase in fluid volumes during the process is equivalent to the production (Dake, 1978). This is due to the fact that no extraneous fluids or gas caps are available to replace the gas and oil*

*Solution gas drive. In a solution (or dissolved) gas drive reservoir, the oil-bearing rock is completely surrounded by impermeable barriers. As the reservoir pressure drops during production, expansion of the oil and its dissolved gas provides most of the reservoir's drive energy . Additional energy is obtained from the expansion of the rock and its associated water.*

*In other instances, as reservoir pressure declines with production, gas evolves in the reservoir (see Solution gas drive reservoirs) and migrates to the top of the structure to add to an existing primary gas cap or to form a gas cap. If properly harnessed, gas caps can enhance oil recovery considerably.*

*Most reservoirs are producing from a combination of two or more drive mechanisms, although one of the drives may be the most active. For example, a reservoir can be driven by water and solution gas at the same time, or with gas cap, rock compaction and water at the same time with one of them being the most dominant.*

*Solution Gas is natural gas which is dissolved in the reservoir along with crude oil, condensates and water. It is also known as dissolved gas as it remains dissolved in the solution until it experiences a pressure and temperature change during the production.*

*Typically, solution gas drive accounts for between 15 – 20 percent recovery of the STOOIP in normal oil reservoirs. Gas cap drive is similar to solution gas drive; however, it only occurs in saturated oil reservoirs (oil reservoirs discovered below the bubble-point pressure of the crude oil). In saturated oil reservoirs, the free gas forms a Gas Cap (portion of the reservoir overlain by free gas due to gravity segregation).*

*Petropedia - What is Solution Gas? - Definition from ...*

*The injection into a solution gas-drive reservoir usually occurs at injection rates that cause re-pressurization of the reservoir. If pressure is high enough, the trapped gas will dissolve in the oil with no effect on subsequent residual oil saturations.*

*Effect of GOR, Temperature, and Initial Water Saturation ...*

*The more gas there is in solution, the more compressible the oil. In oil reservoirs with little or no water drive, reservoir energy to drive the oil toward the wellbore can be supplied by expansion of the oil due to gas expanding in solution. This is a solution gas (or dissolved gas or depletion) drive.*
